Experiment No. 5

Aim:

Performing a transaction using Geth

Theory:

Ethereum Node:

An Ethereum node is a computer that is running the software client. The blockchain network is made up of nodes, which are the only method to access it. Nodes communicate with one another in order to validate transactions and record data about the status of the blockchain.

Types of Node:

- 1. Mining Node: Nodes that belong to miners. These nodes are responsible for writing all the transactions that have occurred in the Ethereum network in the block.
- 2. Ethereum Virtual Machine Node: These are the nodes in the Ethereum network in which SmartContracts are implemented.

By default, this node utilizes a 30303 port number for the purposeofcommunication among themselves.

Process of Mining:

A user writes and signs a transaction request with the private key of some account.

The user broadcasts the transaction request to the entire Ethereum network from some node. Upon hearing about the new transaction request, each node in the Ethereum network adds the request to their local mempool, a list of all transaction requests they've heard about that have not yet been committed to the blockchain in a block.

At some point, a mining node aggregates several dozen or hundredtransaction requests into a potential block, in a way that maximizes the transaction fees they earn while still staying under the block gas limit. The mining node then:

Verifies the validity of each transaction request (i.e. no one is trying to transfer ether out of an account they haven't produced a signature for, therequest is not malformed, etc.), and then executes the code of the request, altering the state of their local copy of the EVM. The miner awards the transaction fee for each such transaction request to their own account.

Department of Computer Science & Engineering (Data Science)

Begins the process of producing the proof-of-work "certificate of legitimacy" for the potential block, once all transaction requests in the block have been verified and executed on the local EVM copy. Eventually, a miner will finish producing a certificate for a block which includes our specific transaction request. The miner then broadcasts the completed block, which includes the certificate and a checksum of the claimed new EVM state.

Other nodes hear about the new block. They verify the certificate, executeall transactions on the block themselves (including the transaction originally broadcasted by our user), and verify that the checksum of their new EVM state after the execution of all transactions matches the checksum of the state claimed by the miner's block. Only then do these nodes append this block to the tail of their blockchain, and accept the newEVM state as the canonical state.

Each node removes all transactions in the new block from their local mempool of unfulfilled transaction requests.

New nodes joining the network download all blocks in sequence, including the block containing our transaction of interest. They initialize a local EVM copy (which starts as a blank-state EVM), and then go through the process of executing every transaction in every block on top of their local EVM copy, verifying state checksums at each block along the way.

What is Geth?

Geth(Go Ethereum) is a command line interface for running Ethereum node implemented in Go Language. Using Geth you can join Ethereum network, transfer ether between accounts or even mine ethers.

Steps to create your own private Ethereum Blockchain:

1. Download Geth and install:

https://geth.ethereum.org/docs/install-and-build/installing-geth#install-on-windows

2. Create a directory to hold your network filesmkdir eth-chain

cd eth-chain

- 3. Create your genesis filetouchGenesis.json
- 4. Open your genesis file and paste the following

```
"nonce": "0x00000000000000042",
```

"timestamp": "0x0", "parentHash":

"extraData": "0x", "gasLimit":

"0xffffffff", "config": { "chainId": 4224,

[&]quot;difficulty": "0x20000", "alloc": {},

```
"homesteadBlock": 0,
"eip150Block": 0,
"eip155Block": 0,
"eip158Block": 0
}
}
```

5. Initial the genesis block

Init our blockchain with the settings in the genesis file and define a folderfor storingchain data. > geth --datadir "./db" init genesis.json

datadir: Data directory for the databases and keystoreinit: initialize a new genesis block

6. Start your Ethereum peer node.

Networkid helps ensure the privacy of your network. You can use any number here(where we used "123456"), but other peers joining your network must use the same one.

```
geth --datadir "./db" --networkid 123456 --http -http.port "8545" - http.corsdomain "*" --nodiscover - http.api="admin,db,eth,debug,miner,net,shh,txpool,personal,web3", -- allow-insecure-unlock
```

7. Attach your terminal to geth in order to interact with blockchain

```
geth attach ipc://./pipe/geth.ipa
```

Department of Computer Science & Engineering (Data Science)

8. Perform various commands. Some of them are given below

admin.nodeInfo

Creates a new account and prints the address. On the console, use:

personal.newAccount("123456")

Note: 123456 is the passphrase.

Check accounts using eth.accounts

Accounts are in an array so you can search account by index.

Use eth.accounts[0]

Check balance of account:

eth.getBalance(eth.accounts[0])

Check balance by using web3

web3.fromWei(eth.getBalance(eth.accounts[0]),"ether")

Mining

a. Set Default Account

Check your default account, type

eth.coinbase

To set your default account, type

miner.setEtherbase(web3.eth.accounts[0])

b. Start mining Check your balance with

eth.getBalance(eth.coinbase)

Run Miner.start(1)

Note: 1 refer to the number of threads

Look at your other terminal window, you should see some mining action in the

logs. Check yourbalance again and it should be higher.

To end mining, typeMiner.stop()

Department of Computer Science & Engineering (Data Science)

10. Transfer

- a. Check your balance eth.getBalance(eth.coinbase)
- b. Unlock account

personal.unlockAccount("eth.accounts[0]")

c. Transfer Ether

```
eth.sendTransaction({from: eth.accounts[0], to:
eth.accounts[1], value: web3.toWei(1, "ether")})
```

Output:

Fig 1: Initializing genesis.json

```
C:\Users\soham\Desktop>mkdir eth-chain

C:\Users\soham\Desktop\eth-chain>geth --datadir "./db" init genesis.json

C:\Users\soham\Desktop\eth-chain>geth --datadir "./db" init genesis.json

> eth.getBalance(eth.accounts[0])
1.125e+21
> eth.getBalance(eth.accounts[0]), "ether")
125
> web3.fromWei(eth.getBalance(eth.accounts[0]), "ether")
0
> web3.fromWei(eth.getBalance(eth.accounts[0]), to: eth.accounts[1], value: web3.toWei(1, "ether")})
Error: authentication needed: password or unlock
    at web3.js:6365:9(45)
    at send (web3.js:6305:9(45)
    at send (web3.js:63099:62(34))
    at <eval>:1:20(21)
```

Note: Authentication is needed to transfer balance. Use personal.unlockAccount(eth.accounts[0])

Observations and Findings: From this we came to know that an Ethereum is a decentralized, open-source blockchain with smart contract functionality. We have also learned about the types of nodes, process of mining and Geth.

Conclusion:

Q. How can you perform a transaction using Geth (the Go Ethereum client) from the command line, and what are the essential steps to send Ether from one account to another?
